Acupuncture: Theory, Efficacy, and Practice

Ted J. Kaptchuk, OMD

Traditionally, acupuncture is embedded in naturalistic theories that are compatible with Confucianism and Taoism. Such ideas as yin-yang, qi, dampness, and wind represent East Asian conceptual frameworks that emphasize the reliability of ordinary, human sensory awareness. Many physicians who practice acupuncture reject such prescientific notions. Numerous randomized, controlled trials and more than 25 systematic reviews and meta-analyses have evaluated the clinical efficacy of acupuncture. Evidence from these trials indicates that acupuncture is effective for emesis developing after surgery or chemotherapy in adults and for nausea associated with pregnancy. Good evidence exists that acupuncture is also effective for relieving dental pain. For such conditions as chronic pain, back pain, and headache, the data are equivocal or contradictory. Clinical research on acupuncture poses unique methodologic challenges. Properly performed acupuncture seems to be a safe procedure. Basic-science research provides evidence that begins to offer plausible mechanisms for the presumed physiologic effects of acupuncture. Multiple research approaches have shown that acupuncture activates endogenous opioid mechanisms. Recent data, obtained by using functional magnetic resonance imaging, suggest that acupuncture has regionally specific, quantifiable effects on relevant brain structures. Acupuncture may stimulate gene expression of neuropeptides. The training and provision of acupuncture care in the United States are rapidly expanding.

For author affiliation and current address, see end of text.
like the earliest Chinese healing, which relied on supernatural guidance or altered states of consciousness, classic Chinese medicine relies on ordinary human sensory awareness. Its fundamental assertion, like the kindred philosophical systems of Confucianism and Taoism, is that contemplation and reflection on sensory perceptions and ordinary appearances are sufficient to understand the human condition, including health and illness. This assertion is fundamentally different from the biomedical viewpoint, which gives privileged status to objective technology and quantitative measurement. Ideally, the scientific analysis penetrates beyond the visible "life world" of the patient, revealing an underlying pathophysiologic disruption, independent from human subjectivity (8).

Despite acupuncture's claim to be based on ordinary perceptions, it is full of strange concepts that can act as formidable barriers (or attractions) to many Westerners. In fact, the foreign-sounding key words of acupuncture—for example, *yin, yang, dampness, wind, fire, dryness, cold,* and *earth*—are ordinary images or patterns (some culturally unique) of a person's state of being and behavior. They represent human "meteorologic" conditions, which are sometimes pathologic and disruptive and sometimes necessary and healthy. They are the fundamental patterns for detecting and synthesizing clinical information. These patterns also create a unique medical thought process.

**Yin-Yang**

Yin and yang are the basic root intuitions of China. They are recognizable in images akin to weather. Yin is associated with cold, darkness, being stationary, passiveness, receptivity, tranquility, and quiescence. Yang is associated with heat, light, stimulation, excess, assertiveness, dominance, movement, arousal, and dynamic potential. These complementary opposites are successively intertwined for additional levels of descriptive refinement.

A simple example is *dampness.* It has the yin qualities of cold, wet, soft, and lingering and also the yang qualities of excessiveness, dominance, heaviness, and "inexhaustible abundance." Acupuncturists claim that dampness is easy to recognize and that it applies to "psychological, ecological, and even moral as well as corporeal phenomena" (9). Some damp signs point to imbalance, or "bad weather," for example, weeping eczema, edema, "slippery" pulse, heaviness in digestion, indecision, clinging, or being helpful to others at the expense of oneself. Some dampness is an essential component of a healthy state of being, for example, smooth skin, normal secretions and excretions, being imperturbable when threatened, generosity, and patience.

In addition to a general synthesis, yin and yang and their climatic subcategories are used to interpret specific subregions of a person's health. These subregions can be different from a person's general meteorologic pattern and can create overlapping domains of yin and yang (for example, yins within yangs) that are as complex as multiple, intersecting circles. Both for the overview pattern and for the subregions, no single sign is conclusive; the overall context defines the parts. Heaviness in digestion or generosity might be "wind" if it appeared in a different configuration of signs. Unlike western medicine, in which signs and symptoms are used analytically to isolate an underlying mechanism, East Asian medicine seeks to discern a *qualitative image* in the overall gestalt or regions of a person's signs and behaviors. Whereas biomedicine aspires toward the scientific and dimensionally measurable *quantitative,* East Asian medicine emphasizes a human-centered approach of artistic impressions and sensitivities (10). If Chinese medicine resembles anything in the West, it would be the prescientific but rational Greek humoral medical system, which also perceived health status in such images of weather as phlegmatic (cold-moist) and choleric (hot-dry) (11).

**Qi**

In traditional acupuncture, the connection between such diverse phenomena as edema and generosity is explained by *qi* (pronounced "chee"). Qi is the linkage in the cosmos that, like the Greek notion of *pneuma,* takes myriad forms. The concept of qi has little scientific cogency, but for the Chinese, it provides a rationale for explaining change and linking phenomena. This rationale unites objective and subjective phenomena and locates disorders in the broadest context of a person's life (12). Whether qi is some kind of "real" quantitative energy in the western sense (akin to 19th century vitalist life-force notions [13]) or a metaphoric way of depicting and experiencing interconnection is not a serious intellectual issue in classic Asian thought (14).

In addition, the target of treatment in Chinese medicine is the state of "disharmony," any imbalance in yin—
ACUPUNCTURE THERAPEUTICS

Imbalances in yin-yang and qi need to be dynamically harmonized. Acupuncture is used to shift a person’s unique “climate.” It can moisten, dry, cool, warm, augment, deplete, redirect, reorganize, unblock, stabilize, raise, or lower a person’s weather patterns. Fine needles are inserted into precisely defined, specific points on the body to correct disruptions in harmony. Heat stimulation, a technique known as *moxibustion*, which burns the herb *Artemisia vulgaris* near the acupuncture point, is sometimes used (especially to warm or move the qi). Hand pressure (“acupressure”) is also sometimes applied. Classic theory recognizes about 365 points, said to be located on 14 main channels (or meridians) connecting the body in a weblike interconnecting matrix. These channels are not detectable by ordinary scientific methods (15). Additional acupuncture points (both on and off the channel) have been added through the millennia, and the total universe of points has increased to at least 2000 (16). In practice, however, the repertoire of a typical acupuncturist may be only 150 points. Traditionally, each acupuncture point has defined therapeutic actions; some points treat an entire yin-yang emblematic configuration, whereas others affect local symptoms. Between 5 and 15 needles are used in a typical treatment, with the point combinations varying during a course of sessions.

China, Japan, and Korea have each developed a distinct version of acupuncture. Thousands of years of history, interpretation, and innovation have produced multiple approaches (17). Specialized acupuncture has also been developed for the ears, scalp, and hands (18). Western nations have developed their own traditions, and one can begin to speak of French (19), British (20), and even American styles of acupuncture (21).

Biomedically trained physicians have developed acupuncture variants that reject “the metaphysical explanations and the necessity for mystical rituals” (22). Their approach emphasizes using acupuncture points based on western understanding of myofascial trigger points, the nervous system, or recent scientific discoveries about the likely mechanism of acupuncture (23). Some approaches used in ancient as well as modern times use standardized “formularies” involving a fixed menu of consistent points for a particular patient’s symptoms, independent of traditional diagnosis. Although more philosophically compatible with biomedicine, these approaches are not entirely disassociated from traditional knowledge. Whether such approaches produce superior clinical results remains to be determined (24).

ASSOCIATED THERAPIES

Acupuncture is often used in conjunction with other modalities. Chinese herbal interventions, which can include animal parts and minerals in addition to botanicals, have historically been the mainstay of East Asian therapy. Although the Chinese materia medica includes more than 5000 entries (25), most practitioners rely on fewer than 250 substances. A body of biomedical literature on Chinese herbal pharmacology, pharmacokinetics, clinical efficacy, and associated adverse events is emerging, and the interested reader can find extensive information elsewhere (1).

Historically, acupuncturists consider the patient-physician relationship and therapeutic encounter itself to be inherently “potent” and sufficient to promote healing (1). In addition, acupuncturists use physical methods, such as massage, cupping (placing vacuum suction over point areas) (26), and scarification (counter-irritation) (27). Lifestyle counseling in such domains as diet, exercise, and mental health is also a component of acupuncture care. Modern *qi-gong*, which is sometimes used by acupuncturists, is a recent healing technique that combines older health and longevity practices (such as breathing and meditation practices) with an amalgam of Chinese religious ideas (28).

SCIENTIFIC EVALUATION OF ACUPUNCTURE

Clinical Evidence

Since the early 1970s, when acupuncture began to capture the popular imagination of the West, almost 500 randomized, controlled trials (RCTs) have evaluated its efficacy (29, 30). More than half were placebo-controlled trials, and the remainder pragmatically compared acupuncture or acupuncture plus conventional care with routine conventional treatment. A growing number of systematic reviews and meta-analyses that use stringent inclusion criteria has begun to synthesize this

research. These reviews most often report that trials of acupuncture efficacy are equivocal or contradictory. Four exceptions are RCTs of acupuncture for emesis and dental pain, which have been overwhelmingly positive, and RCTs of various addictions and tinnitus, which have been predominantly negative. Multiple reviews of identical conditions (for example, asthma or low back pain) generally use overlapping studies and occasionally reach conflicting interpretations. Tables 1 and 2 summarize these studies. The tables are a comprehensive list of all English-language systematic reviews appearing in peer-reviewed journals retrieved from MEDLINE, PsycINFO, Acular, and AMED as well as a compilation of published bibliographies.

In 1997, a National Institutes of Health Consensus Development Panel on acupuncture reviewed the avail-
able evidence from RCTs and reached the following conclusions:

There is clear evidence that needle acupuncture is efficacious for adult postoperative and chemotherapy nausea and vomiting and probably for nausea of pregnancy.

Much of the research focuses on various pain problems. There is evidence of efficacy for postoperative dental pain. There are reasonable studies (although sometimes only single studies) showing relief of pain with acupuncture on diverse pain conditions. However, there are also studies that do not find efficacy for acupuncture in pain.

Although many other conditions have received some

† Review and analysis contain some trials that were not randomized.
The research published after 1997 does not provide significant data to modify or contradict this statement.

Methodologic Issues in RCTs of Acupuncture

With a few important exceptions, RCTs designed to test the efficacy of acupuncture seem to produce contradictory outcomes that resemble random events. Several other treatments that do not involve drugs (especially those for pain, for example, TENS [transcutaneous electrical nerve stimulation], therapeutic ultrasonography, and epidural corticosteroids for sciatica) have similarly confusing results (63). Most systematic reviews of acupuncture have called for higher-quality trials to resolve such inconclusive evidence.

Some of the problems encountered with acupuncture RCTs are shared by RCTs in many domains: insufficient sample size, testing in poorly defined illnesses with imprecise outcomes, vague enrollment criteria leading to heterogeneous study groups, high dropout rates, and inadequate follow-up.

Some of the problems are specifically related to the difficulty in performing RCTs with acupuncture. In RCTs, acupuncturists may have positive expectancy, which is likely to introduce significant bias (64). In many situations, blinding the acupuncturist to avoid such performance bias may be an insurmountable problem (65, 66). The quest for a matching sham control—one that is inert, identical in appearance and sensation, and without nonspecific physiologic effects (such as the release of neurotransmitters, which may affect pain thresholds)—is ongoing (67–70). An inordinately high placebo effect from acupuncture may complicate detection of any intervention–sham difference (71).

Lack of knowledge by researchers may aggravate the problems associated with evaluating the efficacy of acupuncture. For example, the supposedly active acupuncture arm of some RCTs may actually have been more suitable as a dummy treatment (72). How to authentically apply acupuncture-flexible diagnostic categories and process-oriented outcomes within the rigid protocols often necessary for RCTs continues to debate in the research community (73). The heterogeneity of acupuncture techniques themselves challenges researchers: Which category of acupuncture should be tested, and, within each category, how much variability can be allowed (74)? For example, in the asthma RCTs, only two trials by the same author used the same acupuncture points (75). It is probably not an accident that the most unequivocal evidence for acupuncture is based on a series of 30 trials that used a fixed, “druglike,” well-defined research model of a single acupuncture point for a particular symptom (emesis), even though this method has little relevance for the daily practice of acupuncture (76).

Basic-Science Evidence

Numerous surveys show that, of all the complementary medical systems, acupuncture enjoys the most credibility in the medical community (77). The RCT research is probably not the main basis for this positive opinion. A more likely reason is the existence of a substantial body of data showing that acupuncture in the laboratory has measurable and replicable physiologic effects that can begin to offer plausible mechanisms for the presumed actions. Extensive research has shown that acupuncture analgesia may be initiated by stimulation, in the muscles, of high-threshold, small-diameter nerves. These nerves are able to send messages to the spinal cord and then activate the spinal cord, brain stem (periaqueductal gray area), and hypothalamic (arcuate) neurons, which, in turn, trigger endogenous opioid mechanisms. These responses include changes in plasma or corticospinal fluid levels of endogenous opioids (for example, endorphins and enkephalins) or stress-related hormones (for example, adrenocorticotropic hormone) (78).

In one study, the effects of acupuncture in one rabbit could be transferred to another rabbit by cerebrospinal fluid transfusions (79). Although questions remain (80, 81), other studies have shown that acupuncture analgesia could be reversed with naloxone (an endorphin antagonist) in a dose-dependent manner (78, 82). Acupuncture may inhibit early-phase vascular permeability, impair leukocyte adherence to vascular endothelium, and suppress exudative reaction to a degree equivalent to that of orally administered aspirin and indomethacin (83). Evidence also supports the possibility that one mechanism of acupuncture may be a form of stimulation for the gene expression of neuropeptides (84, 85).

Functional magnetic resonance imaging is also be-

Beginning to demonstrate that acupuncture has regionally specific, quantifiable effects on relevant structures of the human brain. One study found that a specific acupuncture point, traditionally related to vision, activated an occipital lobe region that was the same area activated by stimulation of the eye using direct light. The point was located on the lateral aspect of the foot; stimulation of nearby sham points did not result in similar activation (86). Other studies show that specific acupuncture points, but not controls, activate structures of descending antinociceptive pathways and deactivate multiple limbic areas that participate in pain processing (87, 88). These functional magnetic resonance imaging studies follow earlier efforts showing that electro-acupuncture results in significantly increased concentrations in the rat brain (specifically, the occipital cortex and hippocampus) of neuropeptide Y, neurokinin A, and substance P (89).

Adverse Events Associated with Acupuncture

Numerous retrospective clinical reports and at least five published systematic reviews of adverse events associated with acupuncture show that, in rare circumstances, acupuncture can produce the complications associated with any type of needle use (90–96). Negative outcomes include transmission of infectious disease, pneumothorax and other problems associated with organ punctures, cardiac tamponade, and broken needles with remnants migrating to other locations (including the spine). Five incidents may have resulted in death (97), although some researchers refute this possibility (98). Adverse events usually occur when acupuncturists have inadequate training (99).

The reports of adverse events described above are based mainly on retrospective reports. More recently, prospective, systematic surveillances of acupuncture adverse events (which provide a denominator for relative rates) have been performed and indicate that even routine irritating reactions from needles are rare (100–104). For example, one study that followed more than 55,000 treatments at an acupuncture training facility in Japan found 11 adverse effects associated with acupuncture treatment (Table 3) (105). The combined data from prospective and retrospective data indicate that “acupuncture is a very safe intervention in the hands of a competent practitioner” (106).

The Provision of Acupuncture Care in the United States

In 1976, California became the first state to license acupuncture as an independent health care profession. Since then, 40 states and the District of Columbia have adopted similar laws. Most states (27) allow herbal medicine within the scope of acupuncture practice; only a few states (10) require the supervision of a physician for the almost 11,000 practicing nonphysician acupuncturists.

The number of acupuncturists is rapidly growing and is projected to double by 2005 and quadruple by 2015 (107). The typical education standard for an acupuncturist is between 2000 and 3000 hours of training in independently accredited master’s degree 4-year schools. Although some states allow physicians to practice acupuncture without additional education, most states require between 200 and 300 hours of special training. There are approximately 3000 acupuncturists with medical degrees practicing in the United States. Physician and nonphysician acupuncturists independently maintain that their provision of care is superior (108).

In the West, most patients of acupuncture practitioners present with pain resulting from numerous conditions, including musculoskeletal disorders, headaches or migraines, and neuralgia or neuropathy (109–111). Gastroenterologic, urologic, and gynecologic diseases are also fairly represented. Approximately 70% of acupuncturists practice alone or in acupuncture groups; 30% work in multidisciplinary settings, usually in association with other practitioners.
CONCLUSION

In a short time, acupuncture has been transported to the West and become a visible component of the health delivery system. Its traditional conceptual framework is radically distinct from biomedicine. Research on acupuncture has allowed a consensus to emerge that this therapy may have efficacy, regardless of the “prescientific” perspective of its underlying conceptual framework. As an independent profession, acupuncture and East Asian medicine are growing exponentially.
